Different approaches to cloud imagery

- Cameras are considered:**
- Low computational and time cost;
 - Effective and accurate for very short-term forecasting

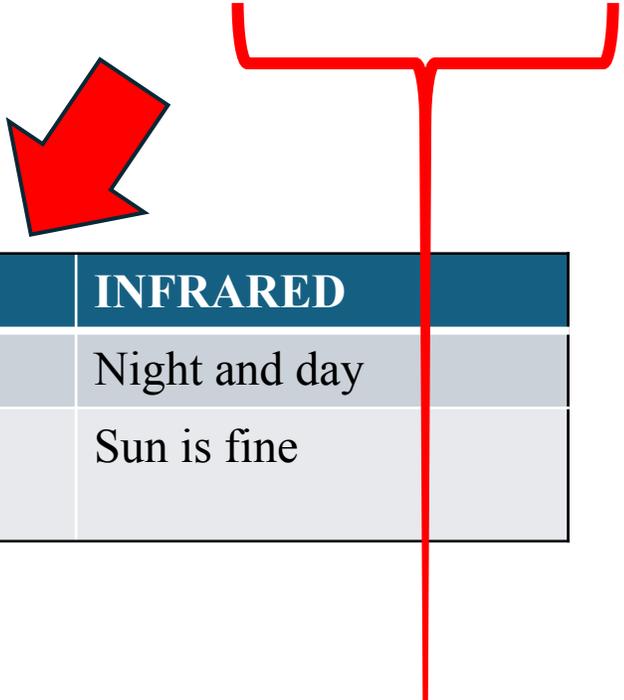

Different
approachs
to cloud
imagery

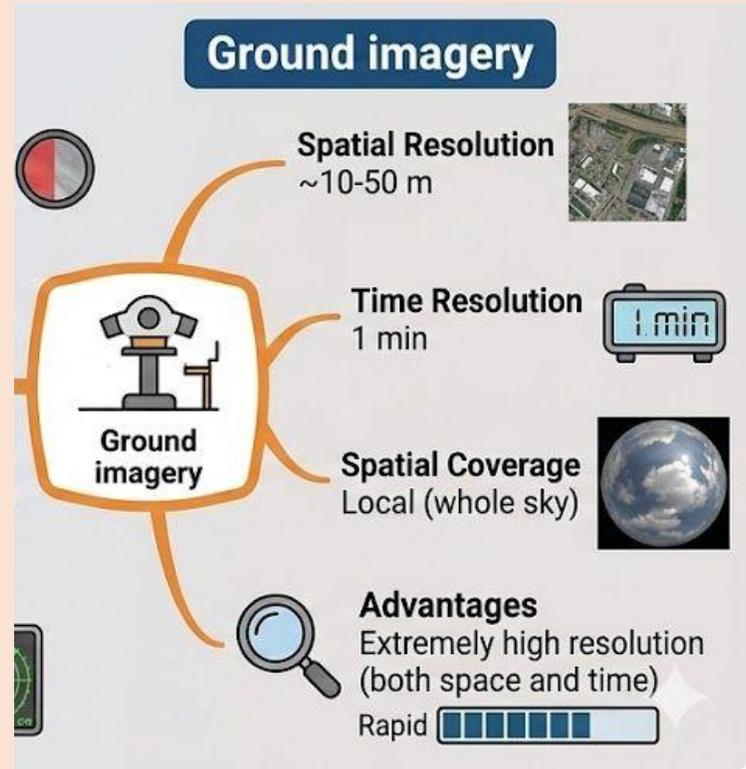

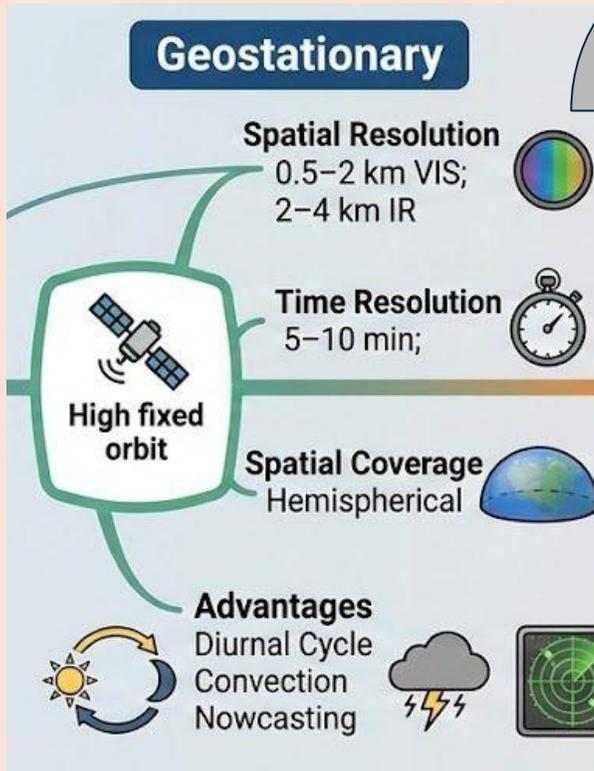

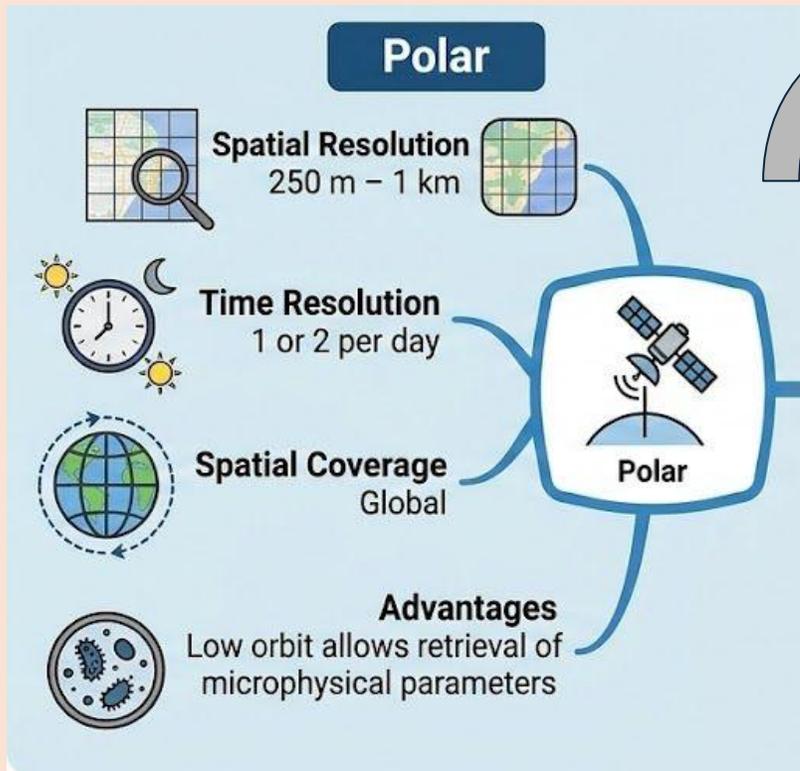

Feature	Polar	Geostationary	Ground imagery
Spatial resolution	250 m – 1 km	0,5–2 km VIS; 2–4 km IR	~10-50 m
Time resolution	1 or 2 per day	5–10 min;	1 min
Spatial Coverage	Global	Hemispherical	Local (whole sky)
Advantages	Low orbit allows retrieval of microphysical parameters	Diurnal Cycle Convection Nowcasting	Extremely high resolution (both space and time)

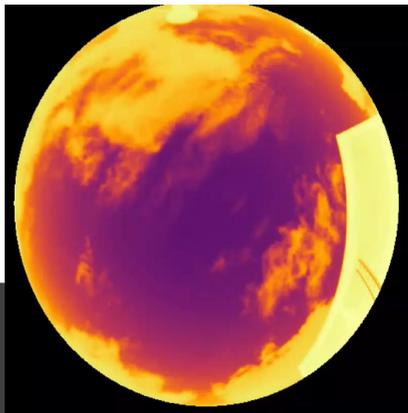

Different approaches to cloud imagery

Feature	Polar	Geostationary	Ground imagery
Spatial resolution	250 m – 1 km	0,5–2 km VIS; 2–4 km IR	~10-50 m
Time resolution	1 or 2 per day	5–10 min;	1 min
Spatial Coverage	Global	Hemispherical	Local (whole sky)
Advantages	Low orbit allows retrieval of microphysical parameters	Diurnal Cycle Convection Nowcasting	Extremely high resolution (both space and time)

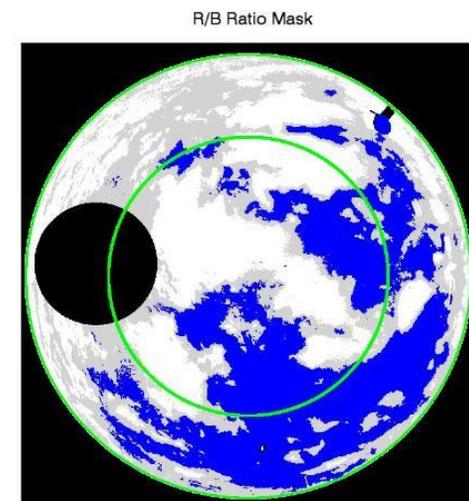

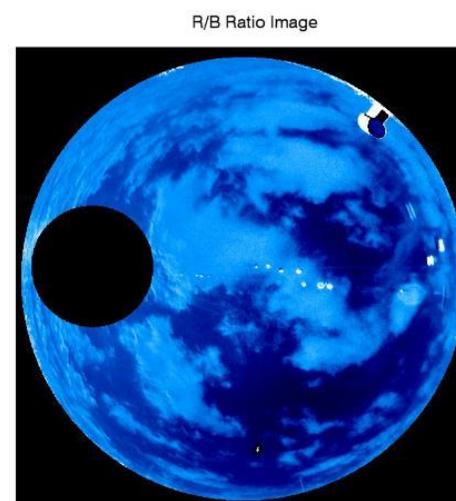

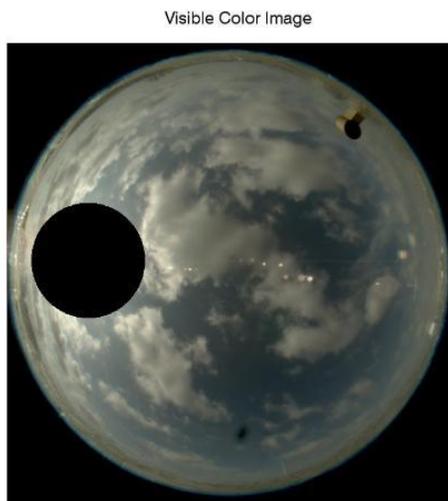

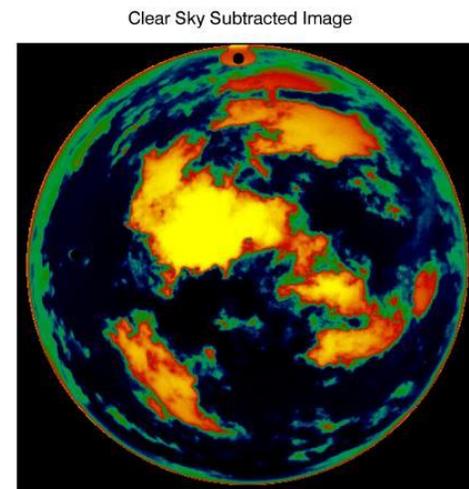

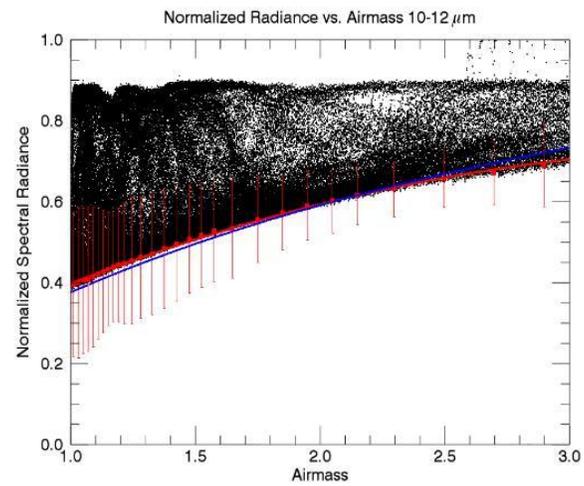

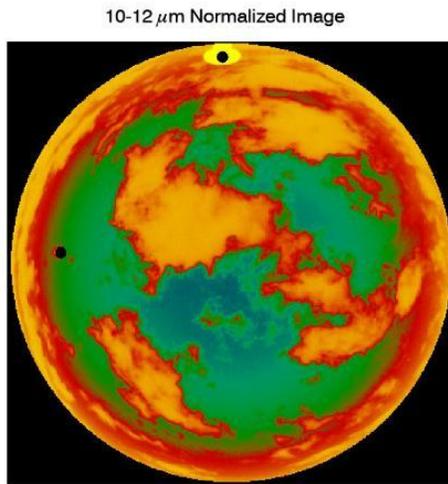

VISIBLE	INFRARED
Day time only	Night and day
Difficulties with sun bright	Sun is fine

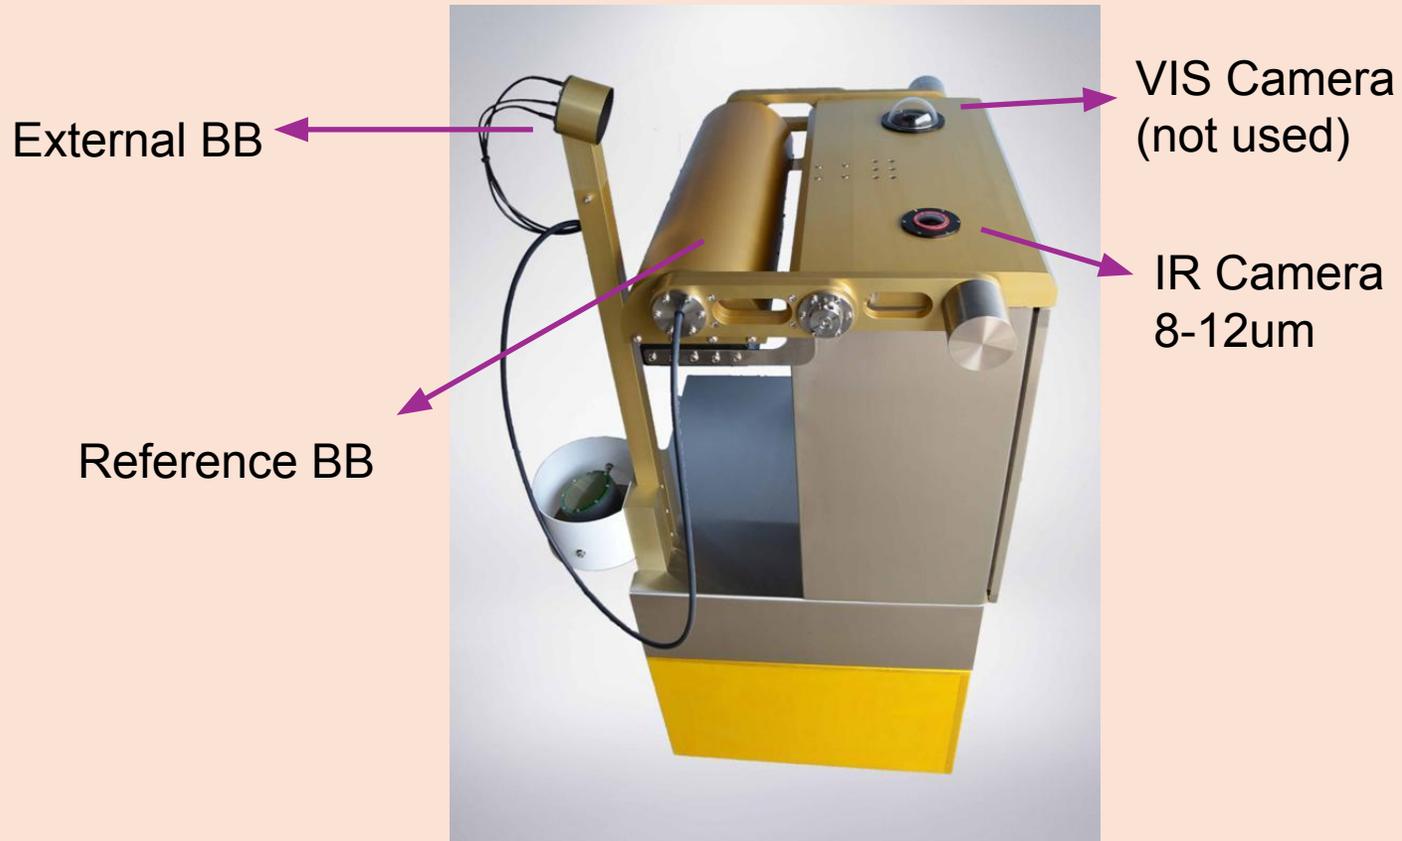

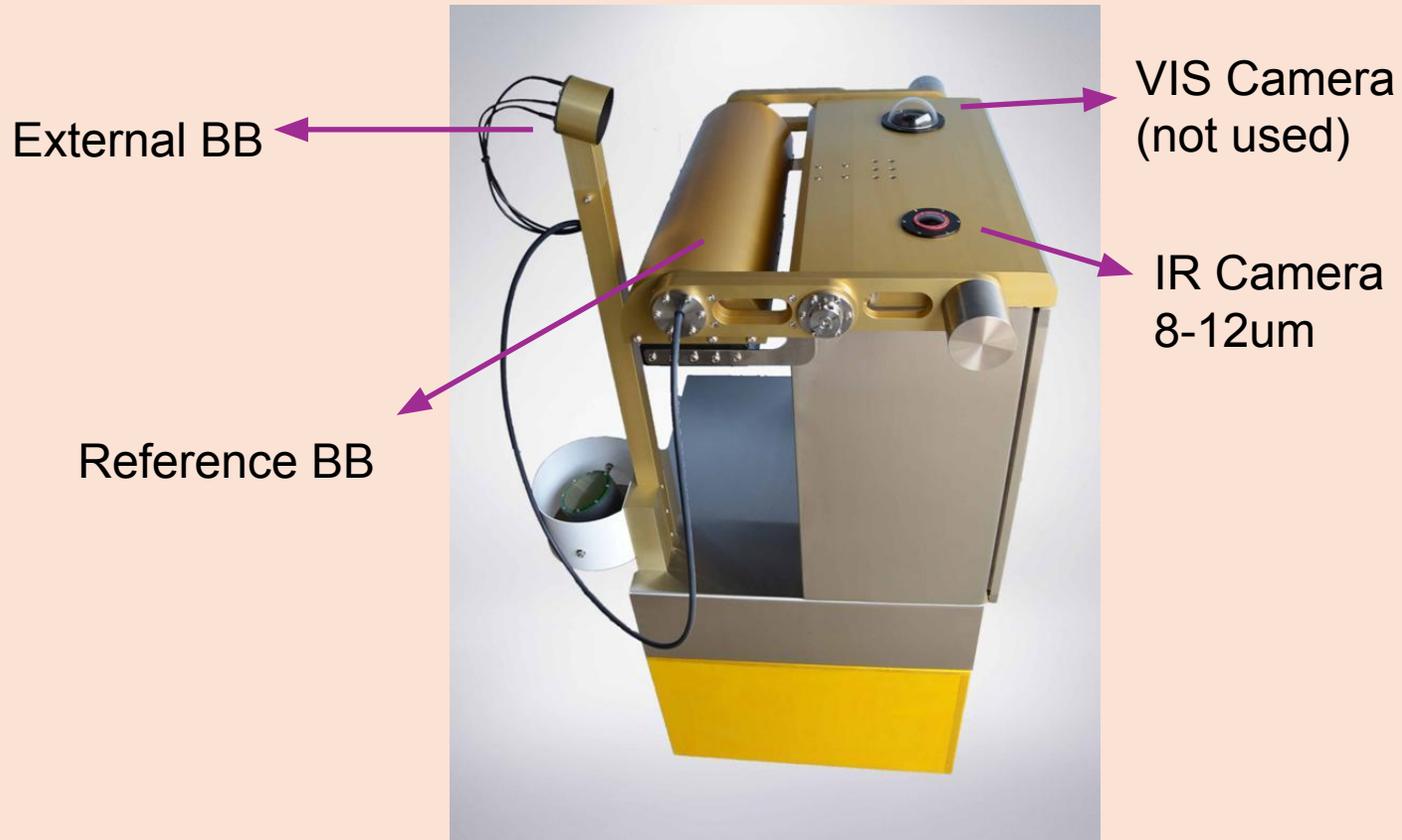

Imagery
of clouds
from the
ground:

Our measurements (methods):

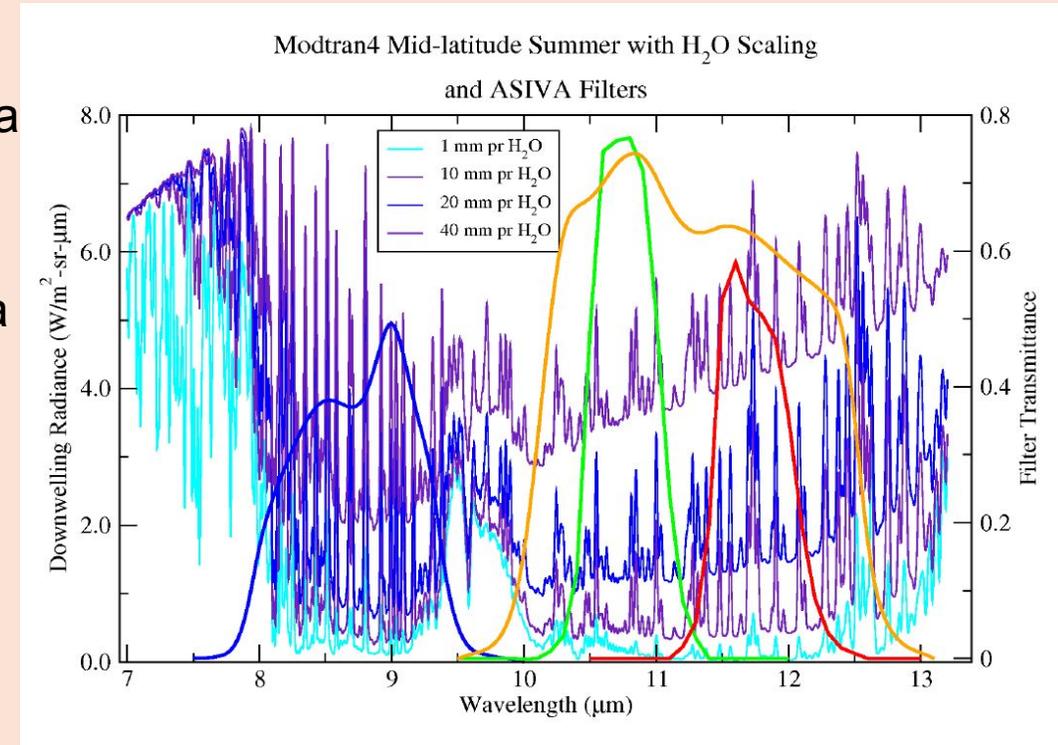

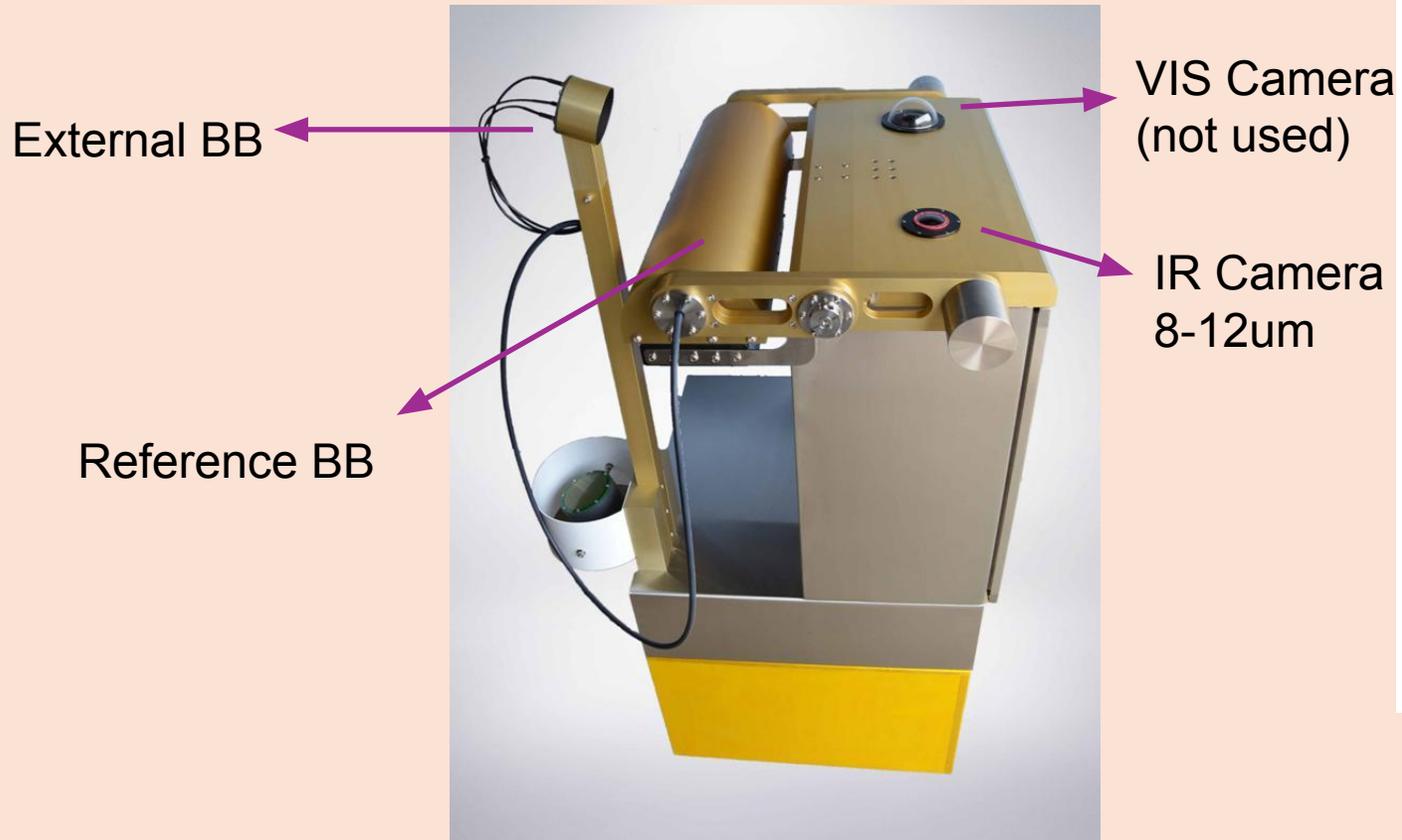

Our measurements (methods):

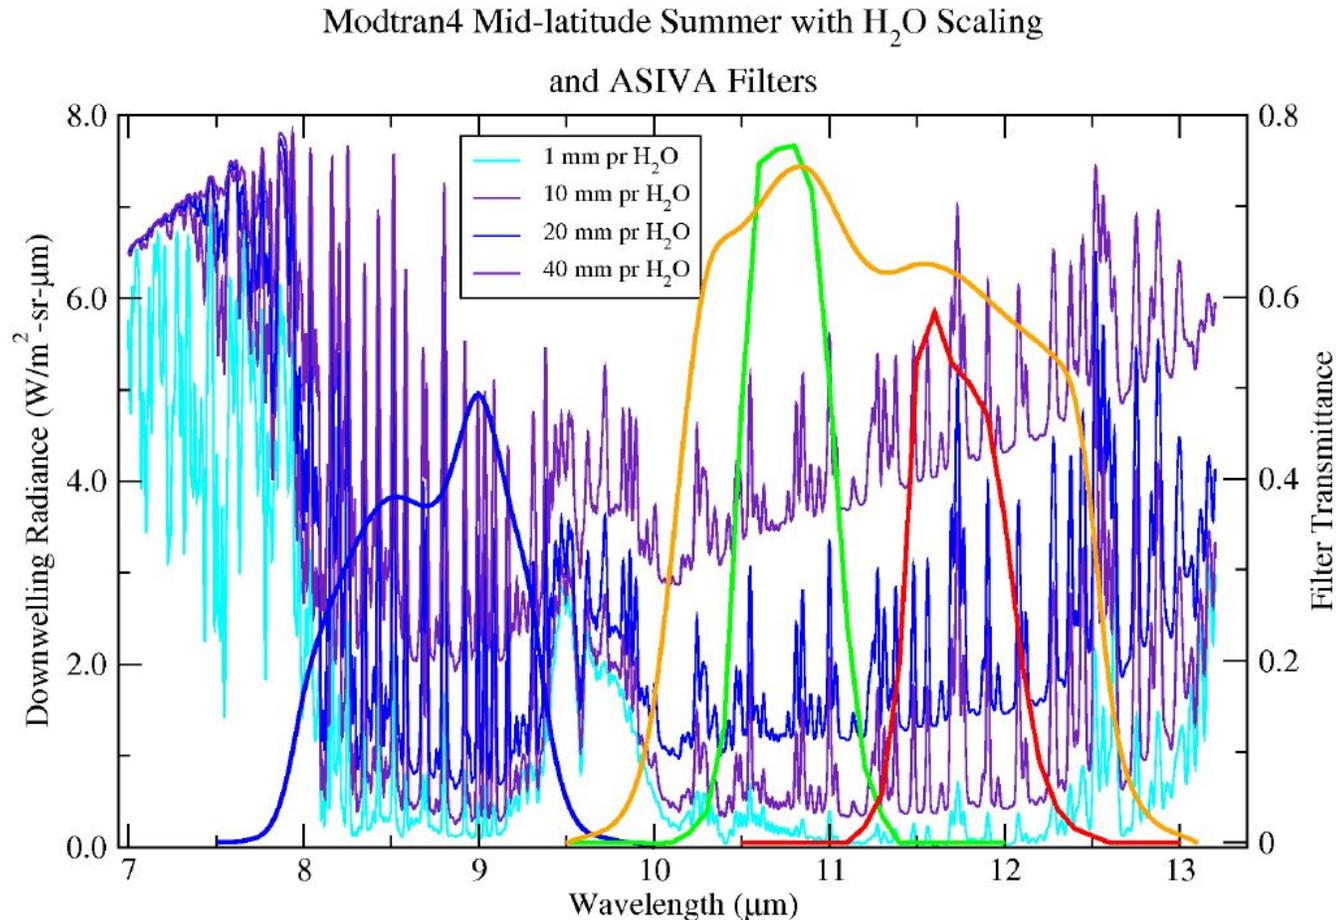

- Camera is (previously) absolutely calibrated with a reference Black Body;
- Coordinates in the image (zenithal angles, altitude and azimuth) are calibrated with astronomical procedure.

Our measurements (methods):

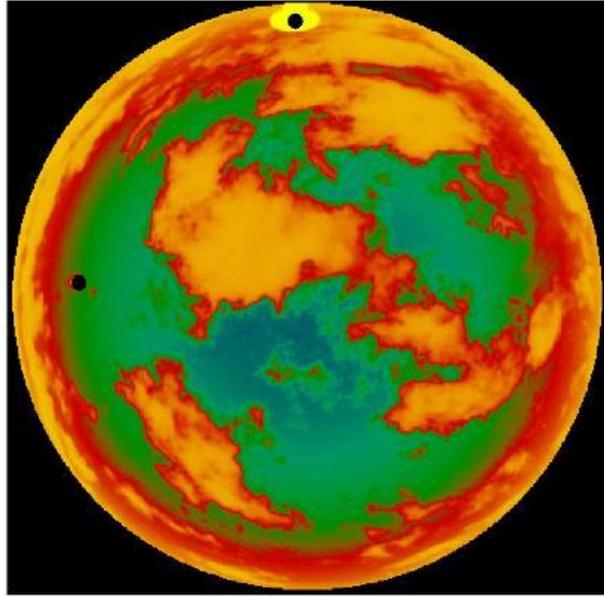

Spectral region:

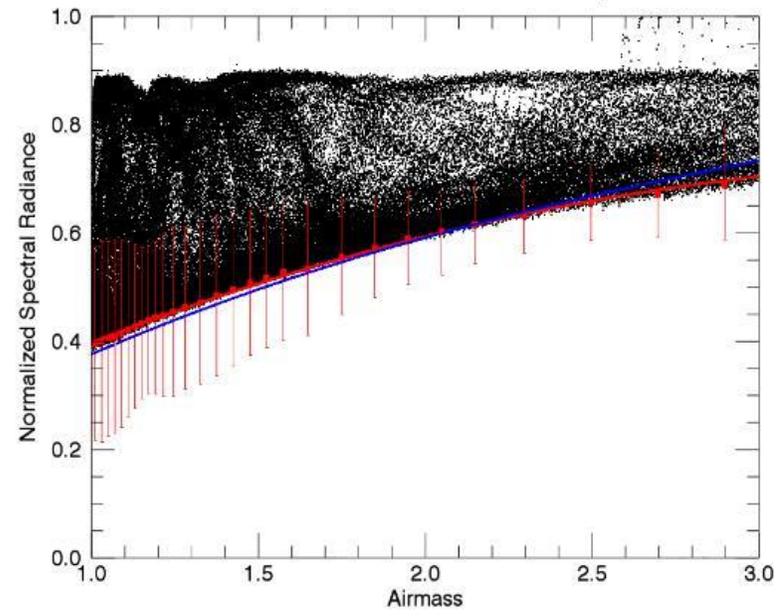

- Two basic channels:
 - 8-9 μm (CH1)
 - 10-12 μm (CH4)
- Background: water vapor (should be removed!)

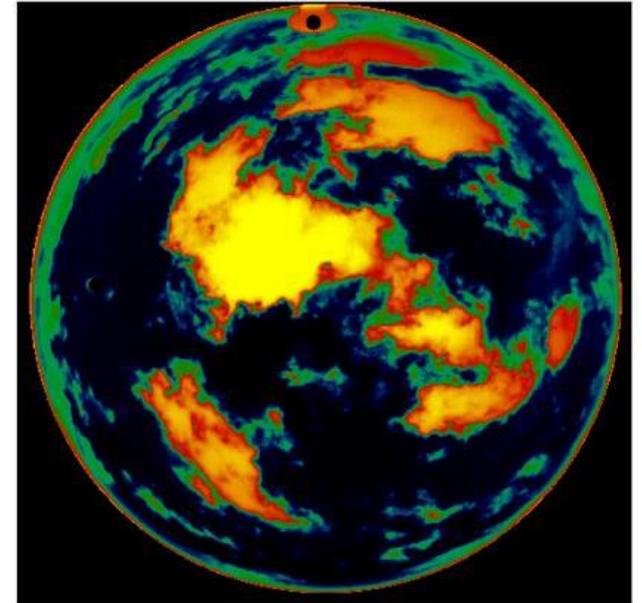

10-12 μm Normalized Image

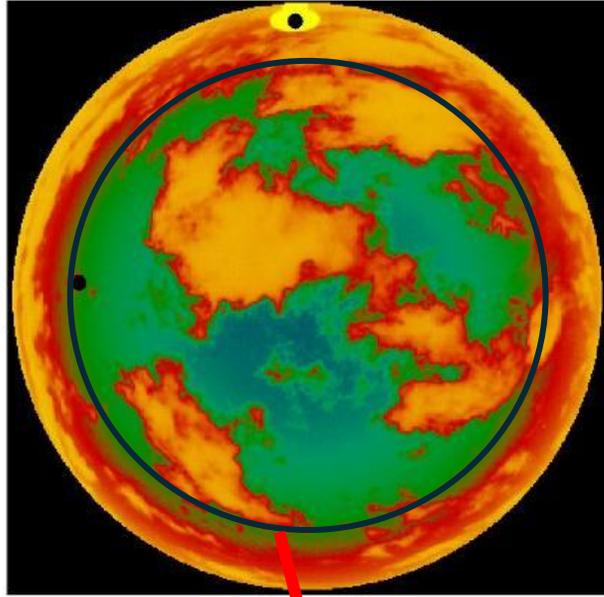

Normalized Radiance vs. Airmass 10-12 μm

Clear Sky Subtracted Image

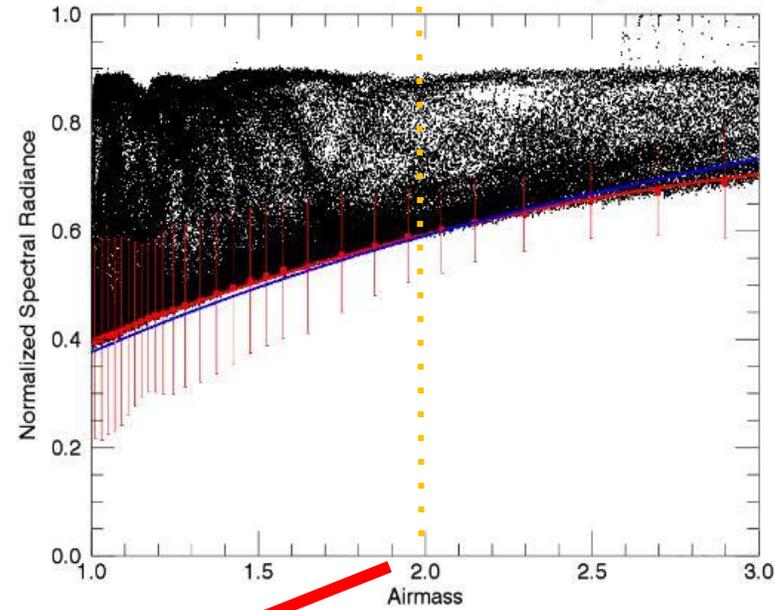

10-12 μm Normalized Image

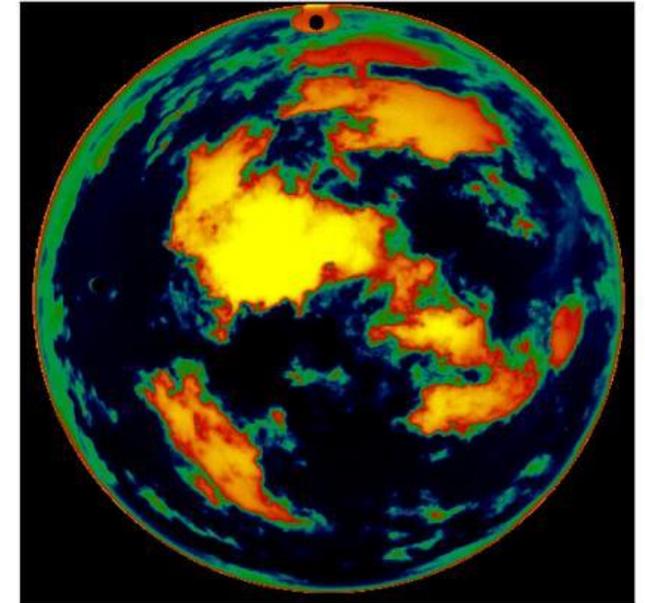

2 airmasses

Normalized Radiance vs. Airmass 10-12 μm

Clear Sky Subtracted Image

The main challenge: to fit the clear sky emission.

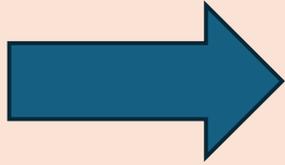

Possible approaches:

- Fit bottom envelope (when extra data absent);
- Atmospheric sounding (when available) >>> LibRadTran;
- Reanalysis profile >>> LibRadTran.

Manaus (central Amazon, urban site, DRY SEASON)

What we get
in the very
end:

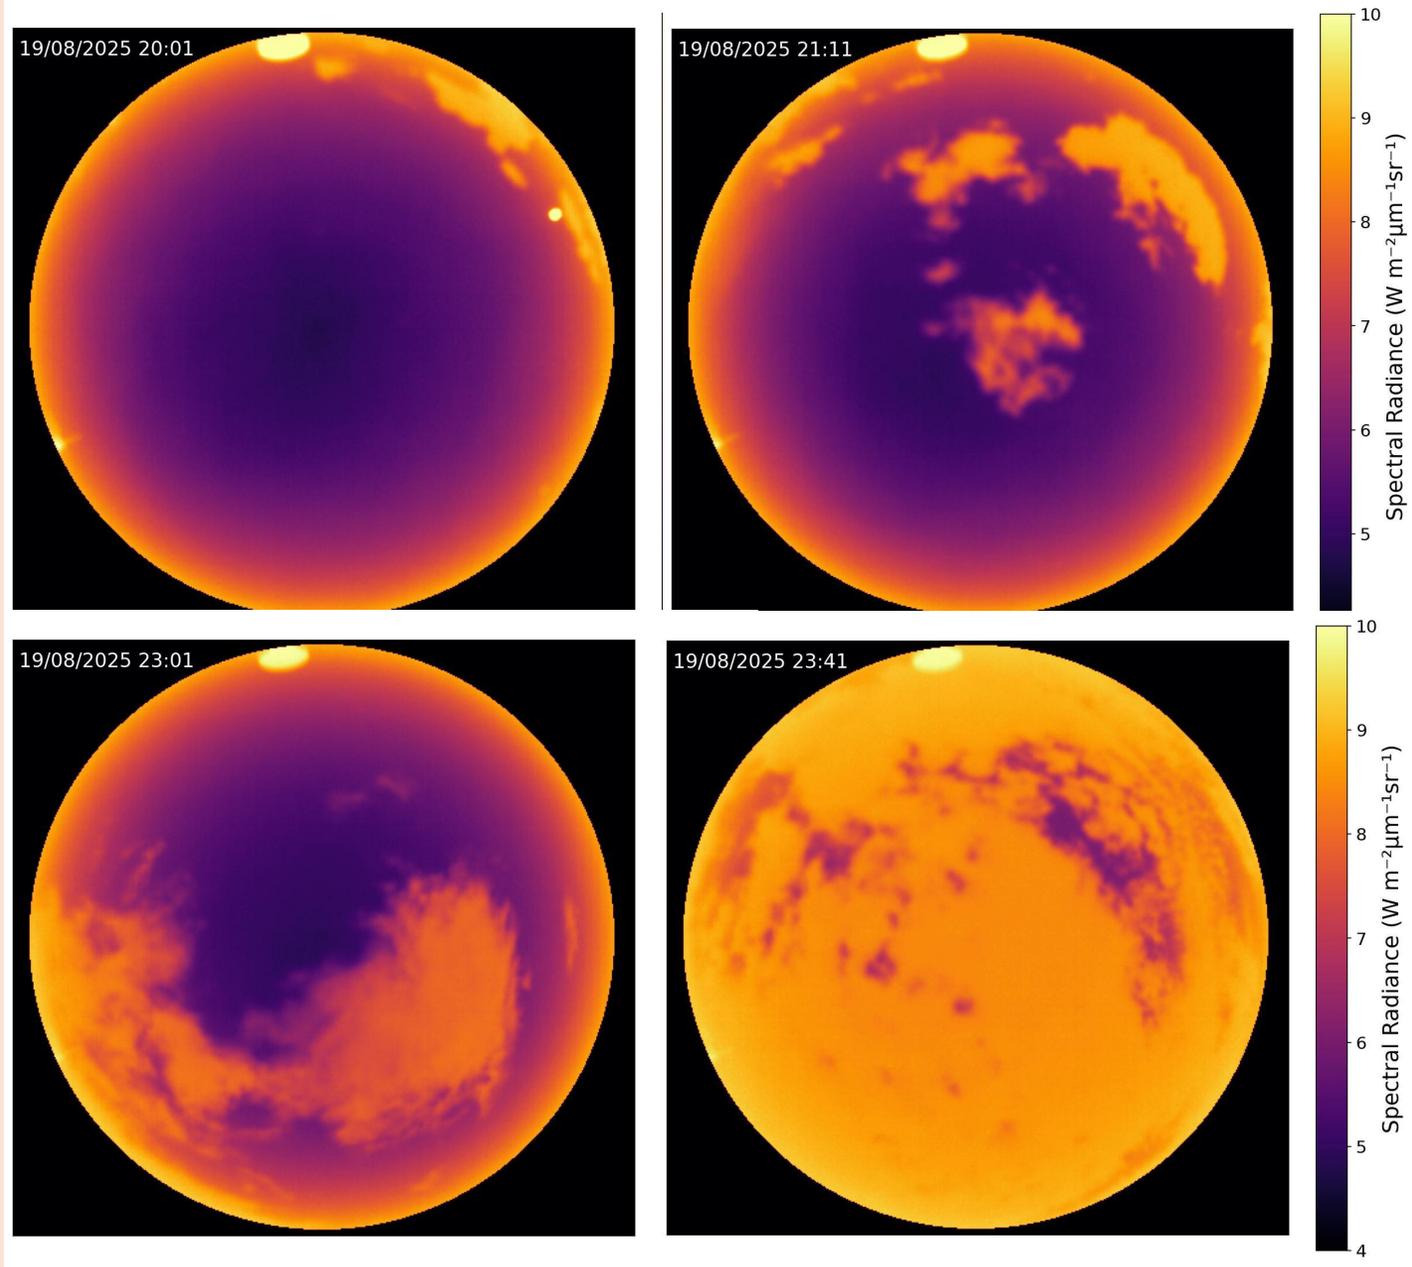

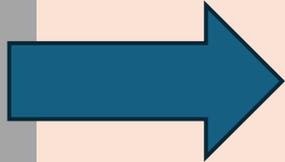

- Spectrally
calibrated
radiance

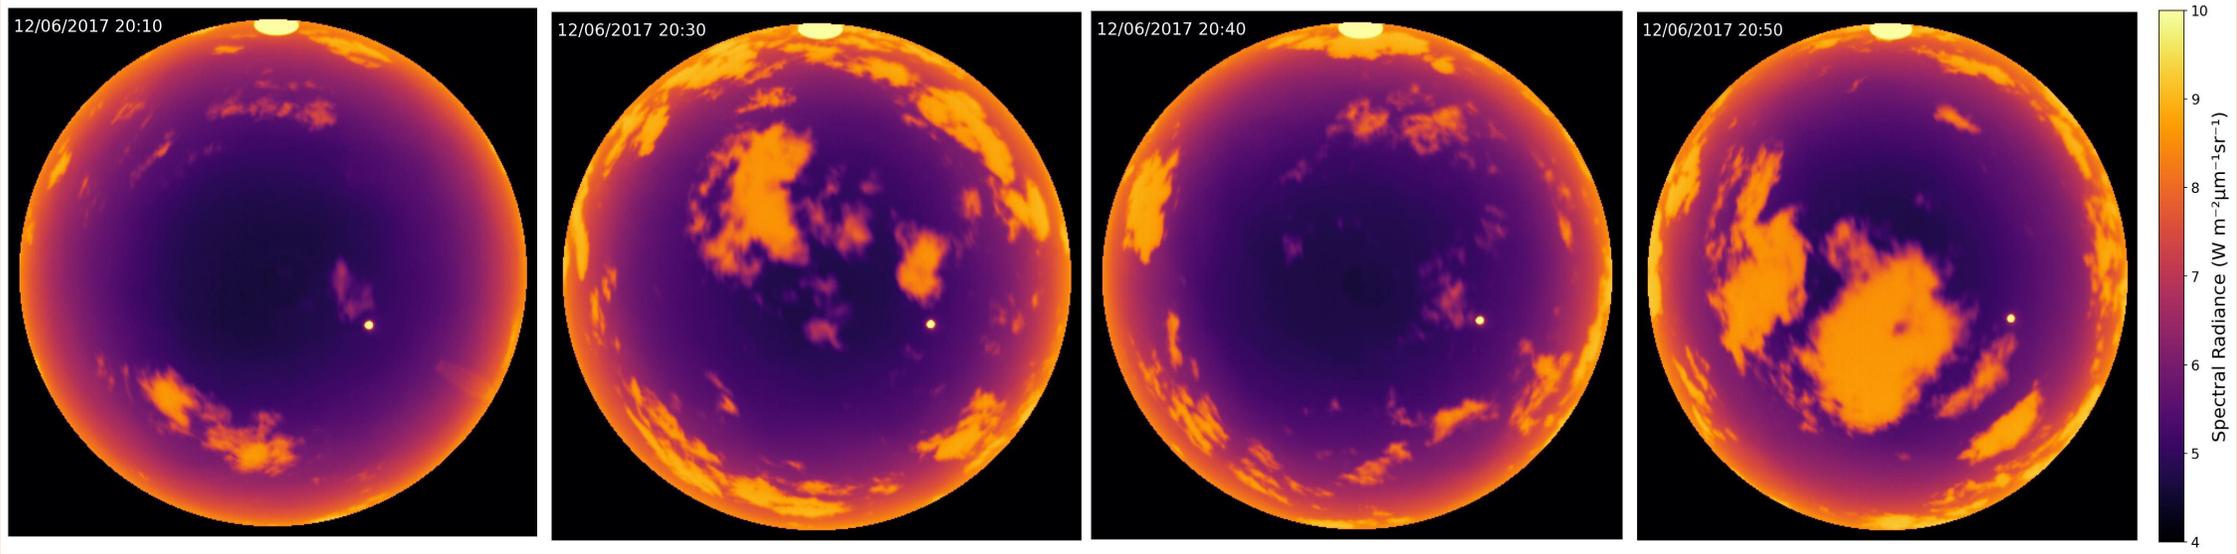

Manaus (central Amazon, urban site, DRY SEASON)

What we get in the very end:

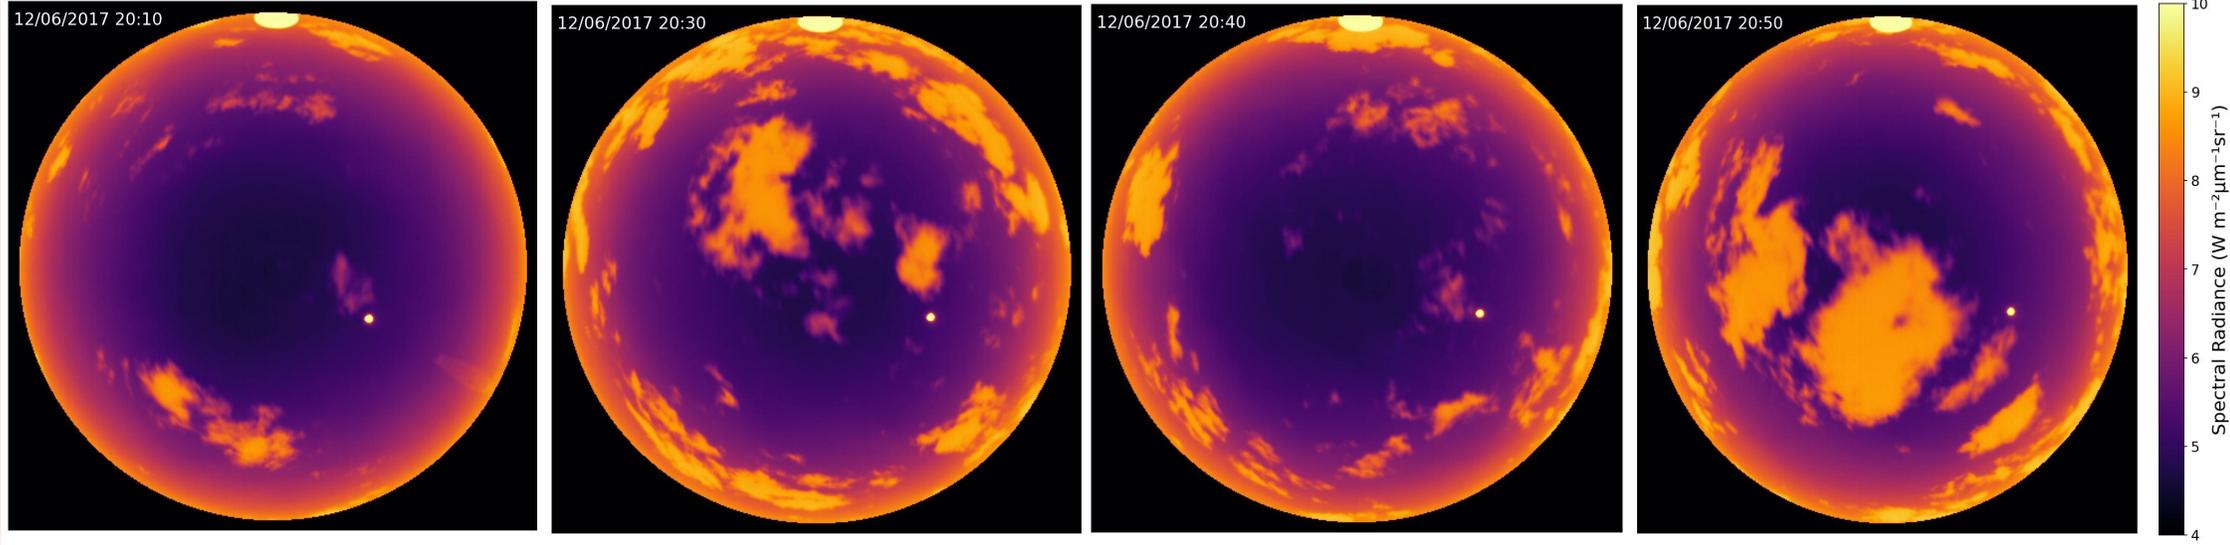

- Spectrally calibrated radiance

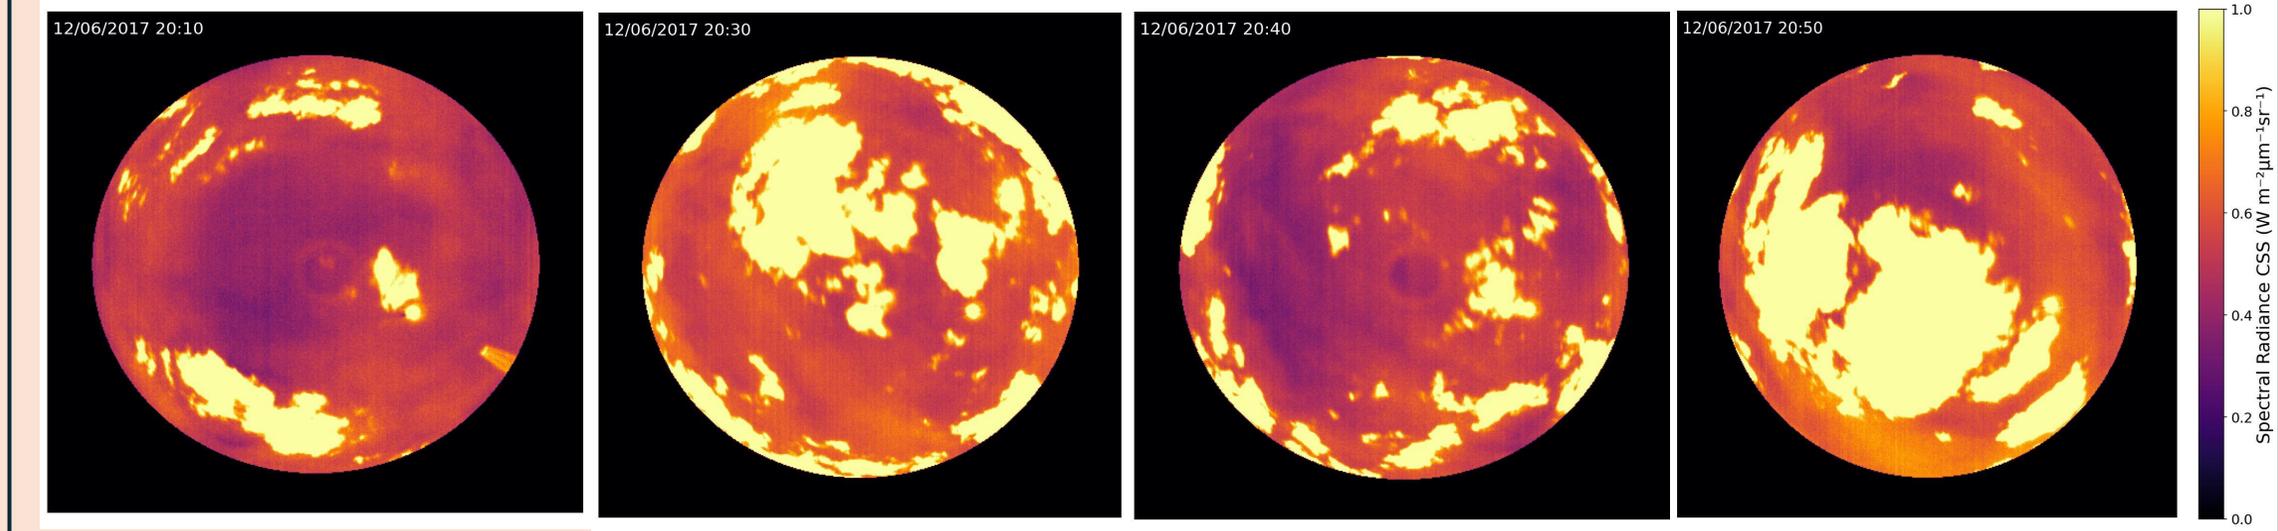

Actual Radiance field (as function of zenithal angle)

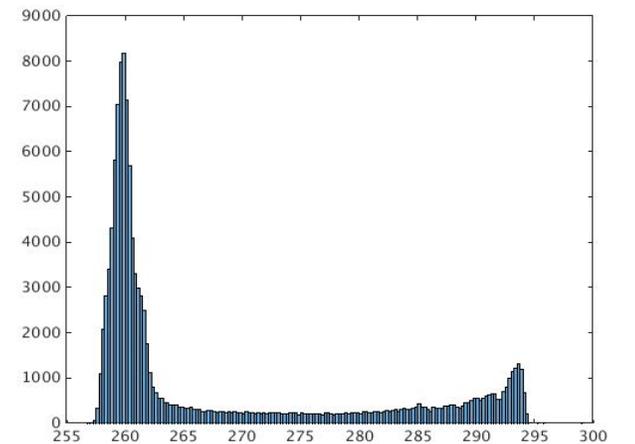

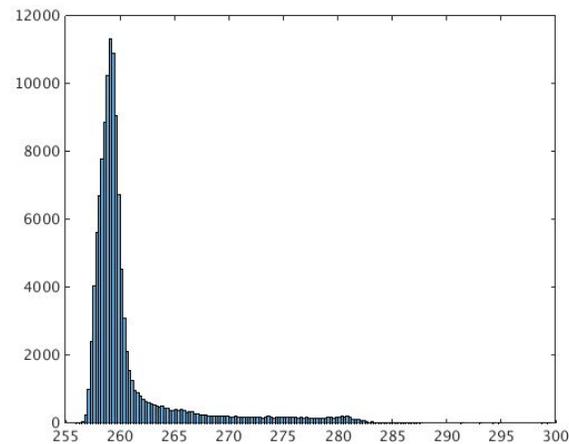

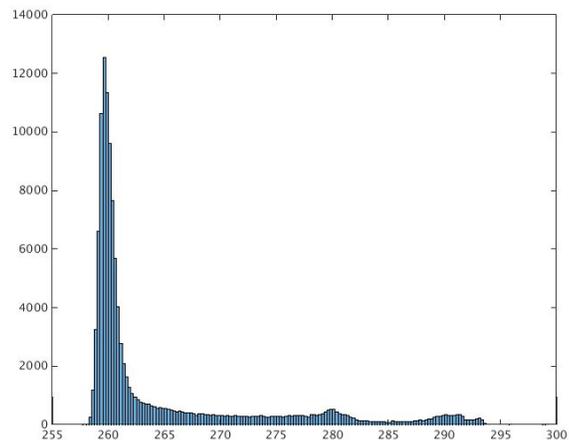

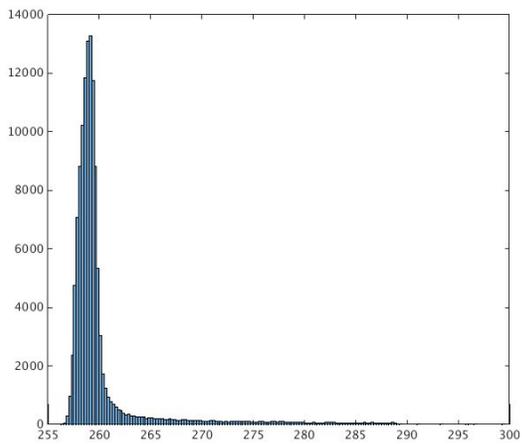

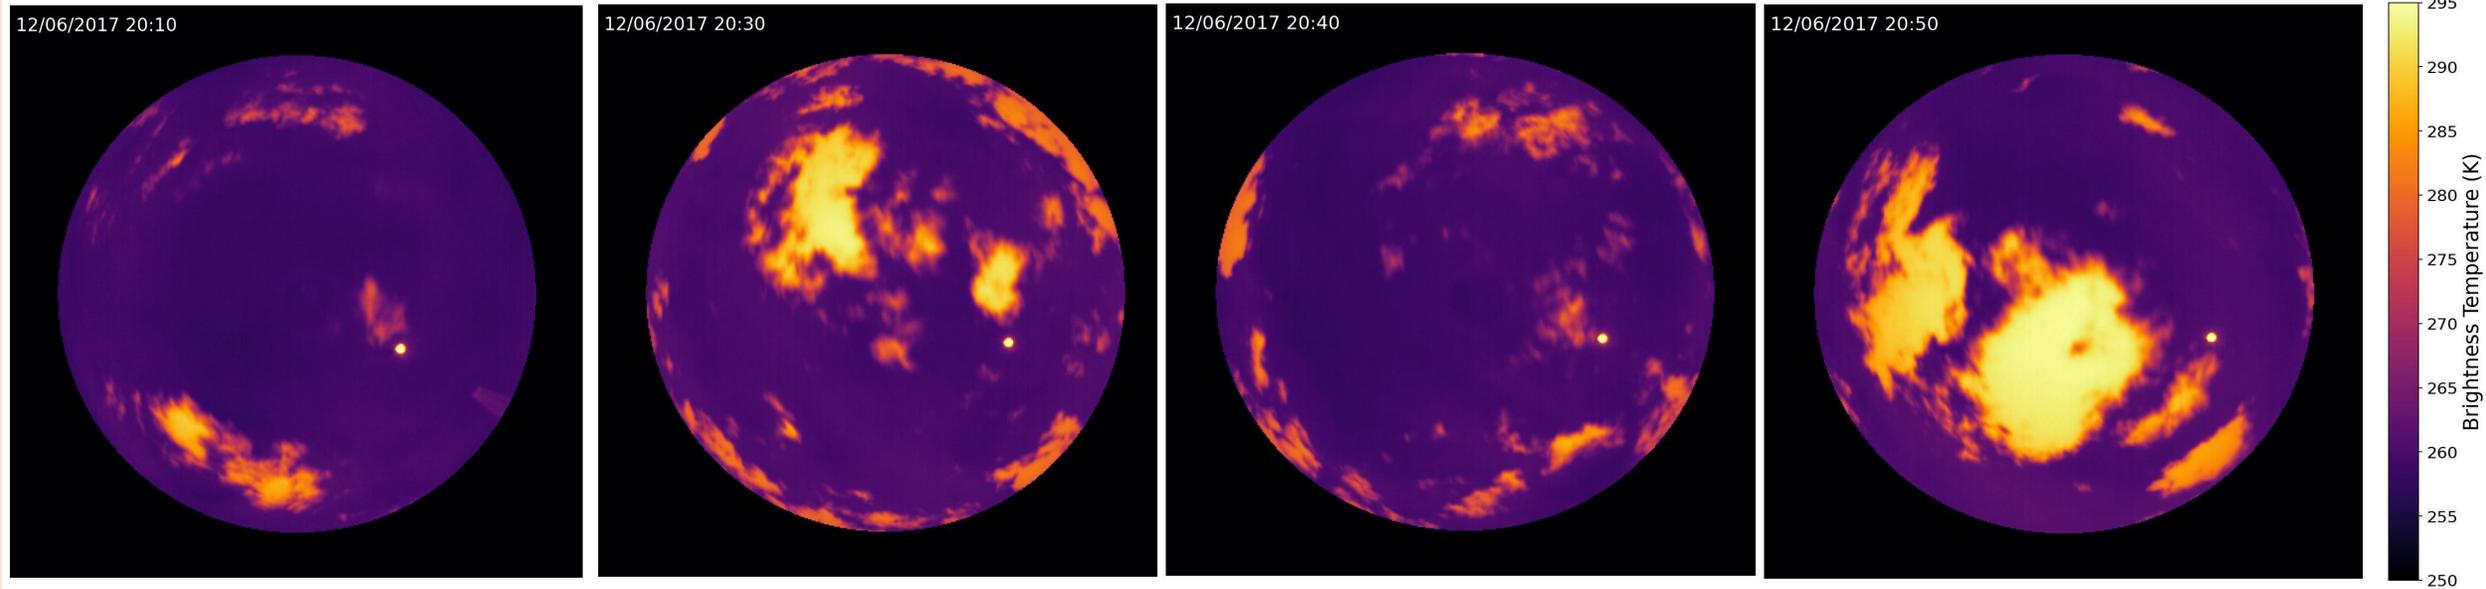

Actual Radiance field (as function of zenithal angle)

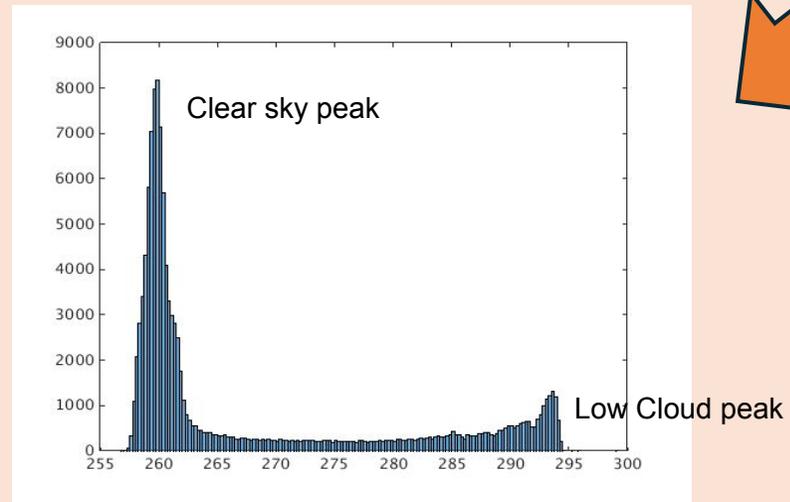

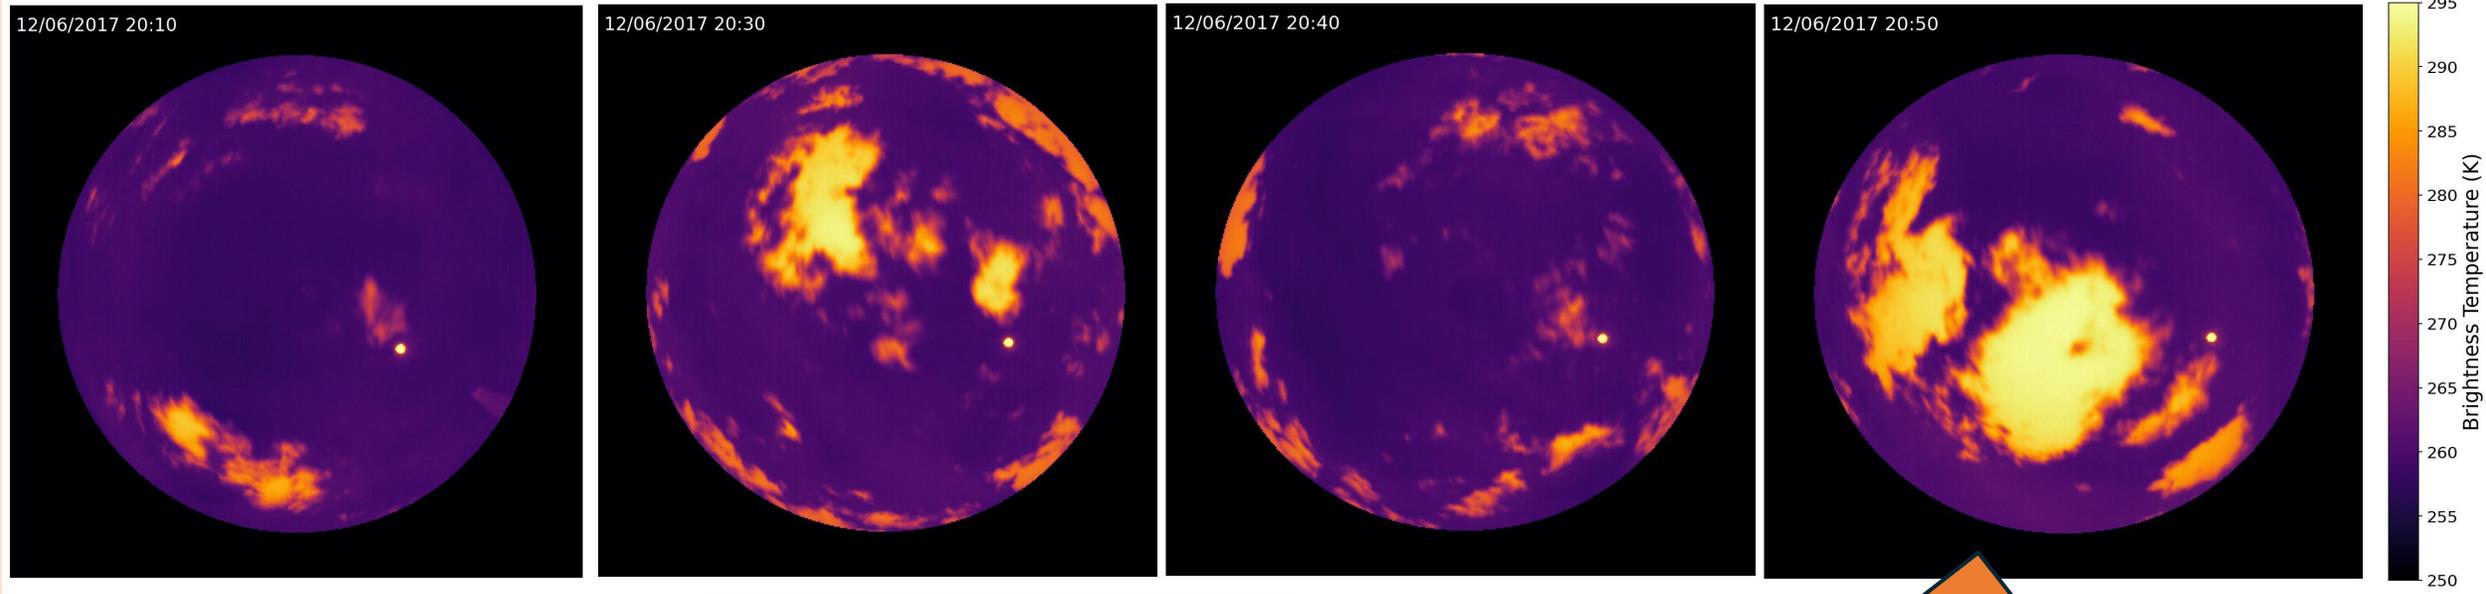

Clear Sky Subtracted Radiance: *proxy for cloud mask*

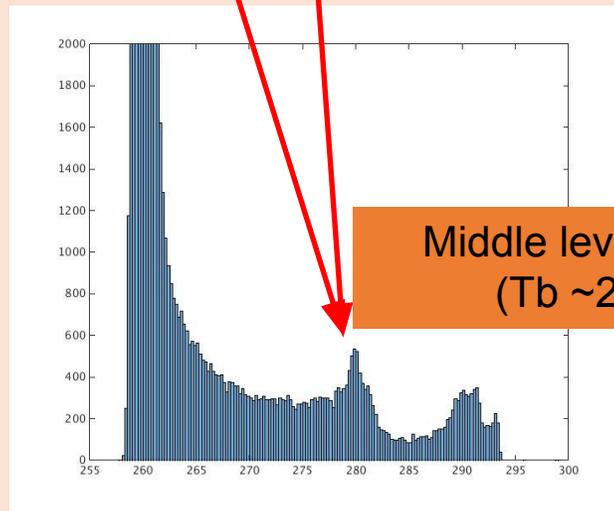

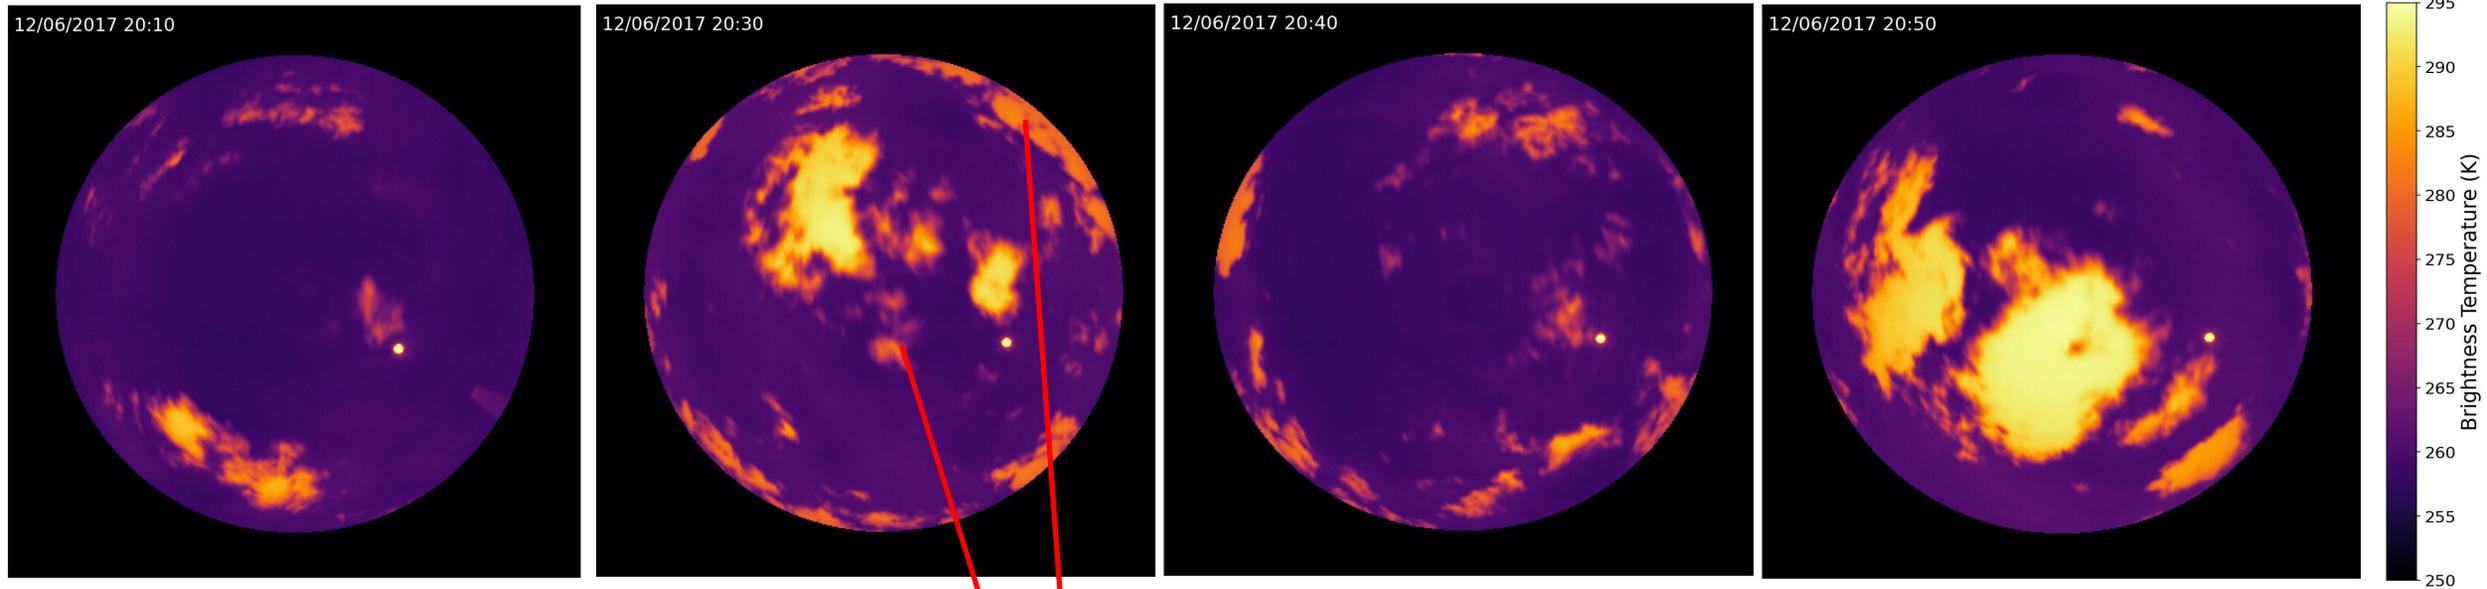

• Brightness Temperature: *Proxy for cloud base height*

• Brightness Temperature: *Proxy for cloud base height*

• Brightness Temperature: *Proxy for cloud base height*

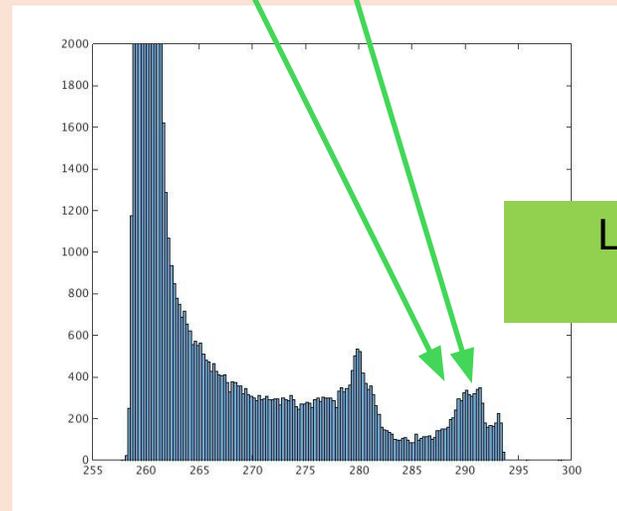

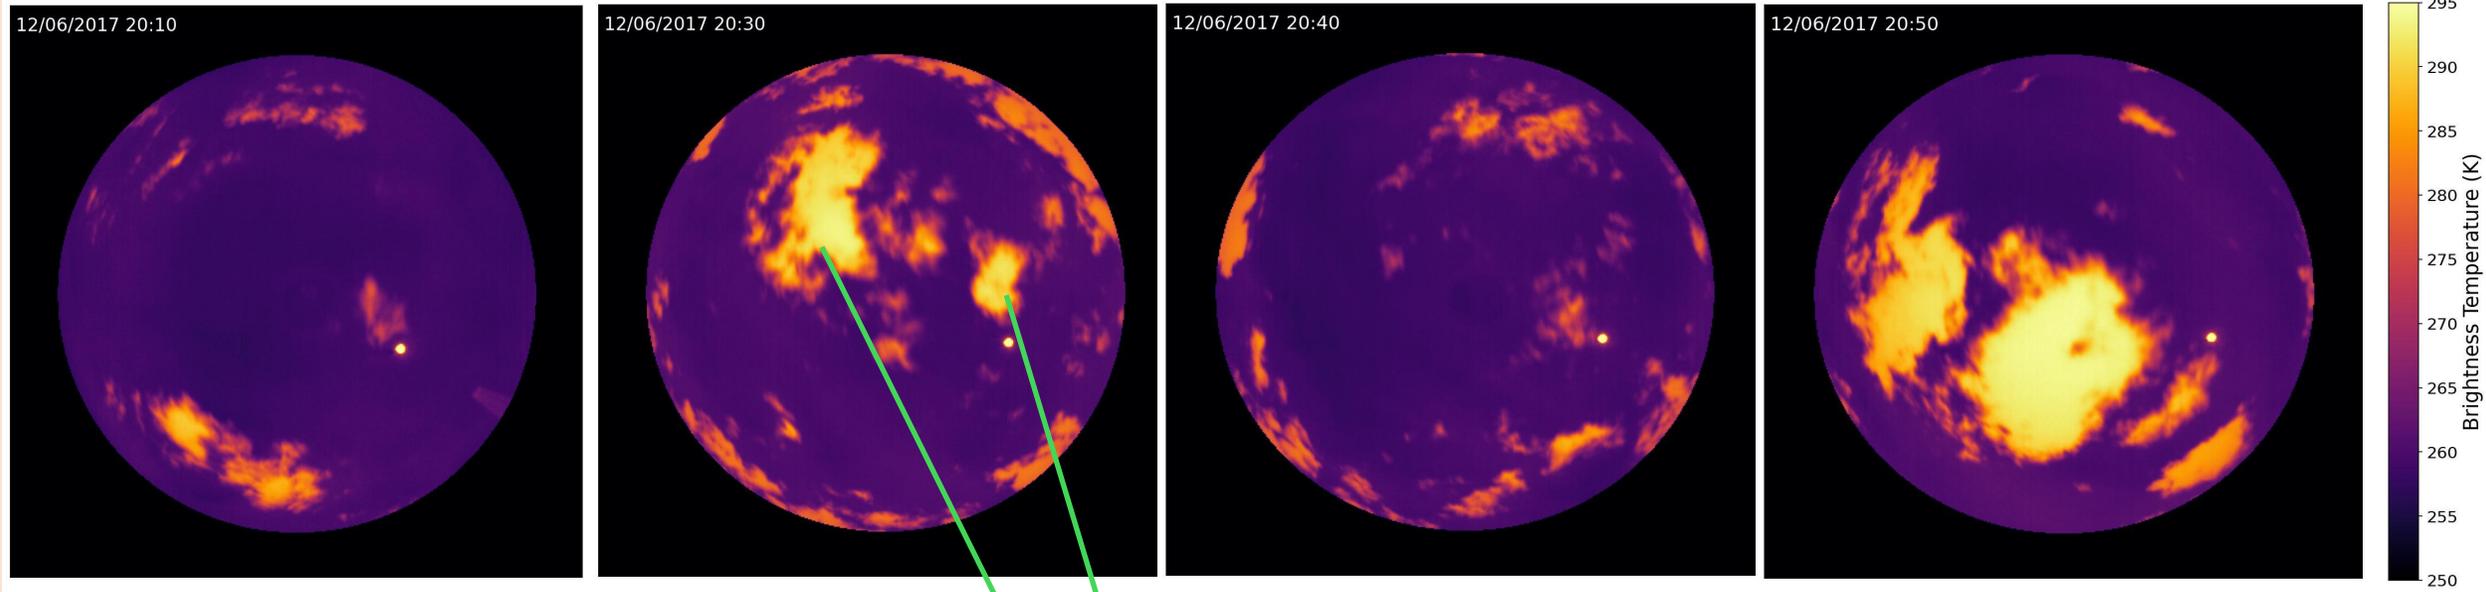

Middle level clouds
($T_b \sim 280\text{K}$)

Temp Ambient $\sim 309\text{K}$!

Zoomed Histogram

• Brightness Temperature: *Proxy for cloud base height*

Low level clouds
($T_b \sim 292\text{K}$)

Temp Ambient **$\sim 309\text{K}$** !

Zoomed Histogram

Potential applications in modelling:

- Validation of Cloud Resolving simulations:
 - 1 minute gridded fields of:
 - Cloud radiance; Clear Sky Radiance.
 - Cloud mask;
 - Cloud Base downward IR radiance
 - Horizontal domain: ~40 km

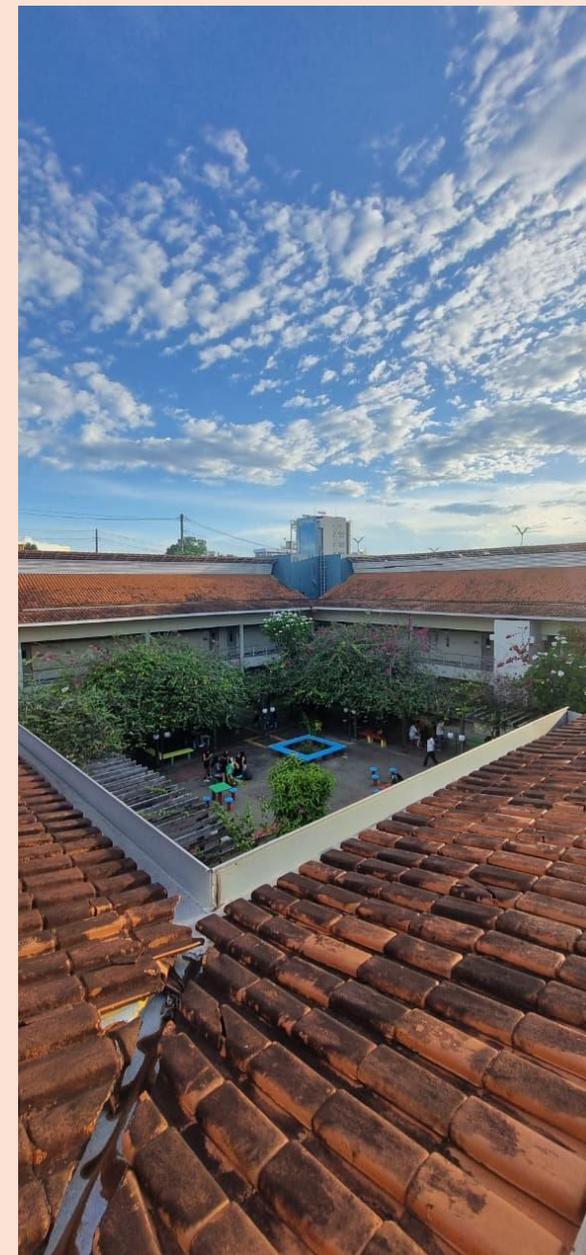

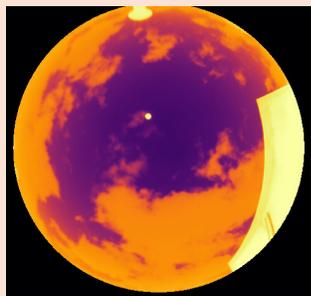

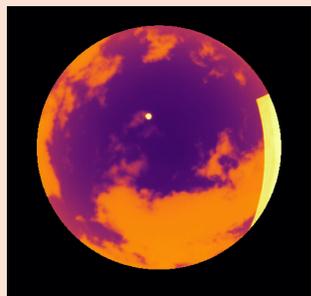

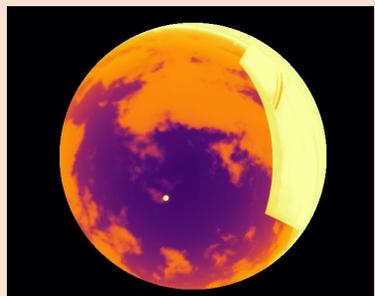

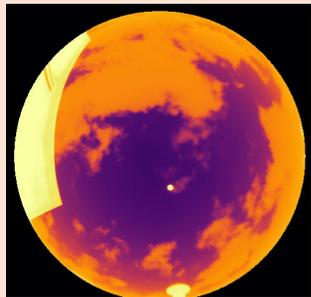

Other applications for this technique:

- Cloud effect of Solar Power Plants;
- Laser communication;
- Astronomy;
- Military.

REMOTE SENSING PLATFORMS
A FEATURE COMPARISON

Polar

High fixed orbit

Ground imagery

Spatial Resolution
250 m – 1 km

Spatial Resolution
~10-50 m

Time Resolution
1 or 2 per day

Spatial Resolution
0.5–2 km VIS;
2–4 km IR

Time Resolution
5–10 min;

Time Resolution
1 min

Spatial Coverage
Global

Spatial Coverage
Hemispherical

Spatial Coverage
Local (whole sky)

Advantages

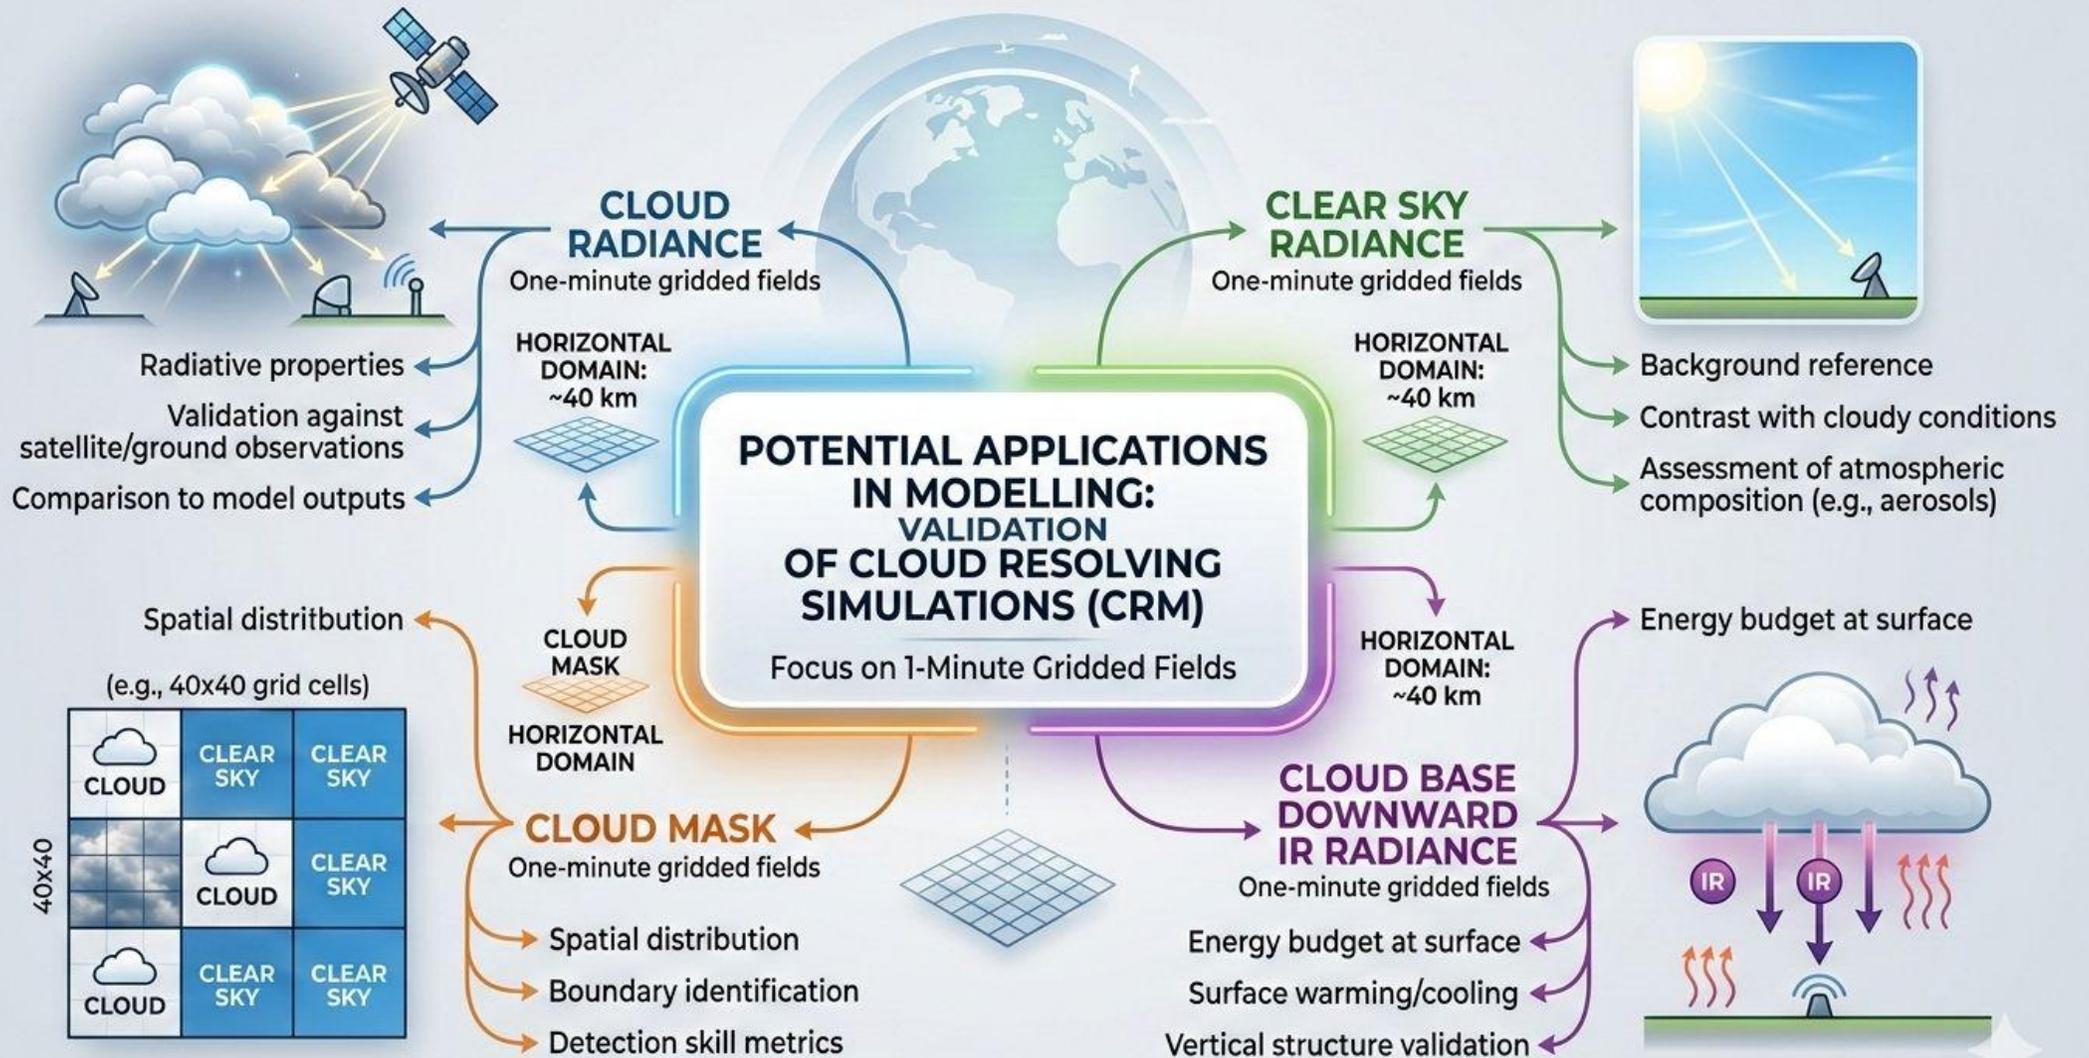

Low orbit allows retrieval of microphysical parameters

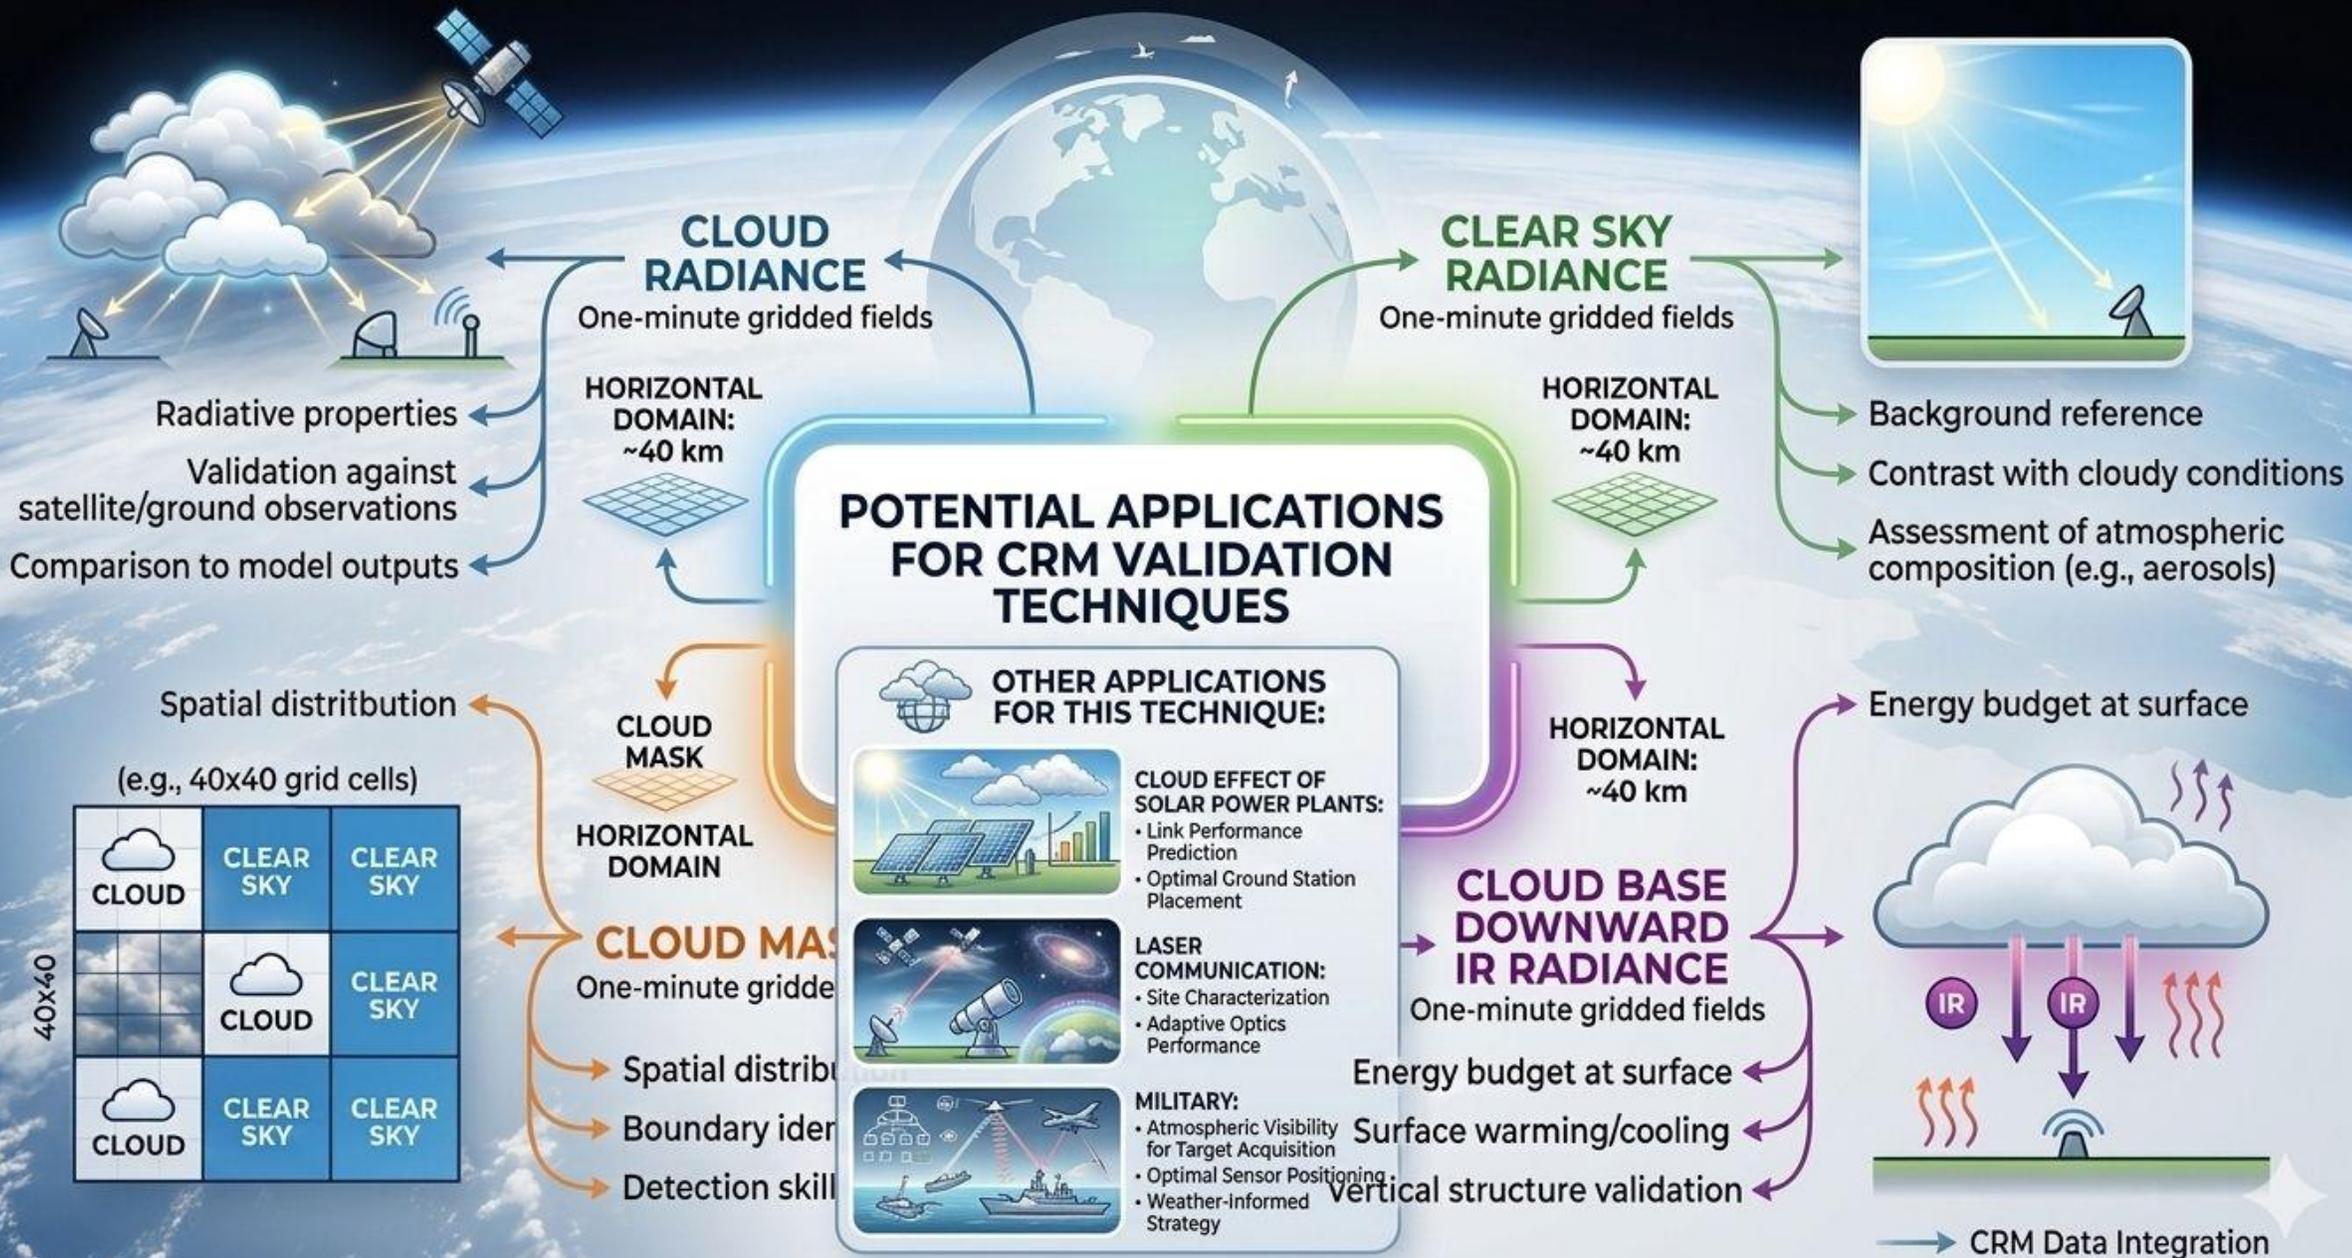

Advantages

Diurnal Cycle
Convection
Nowcasting

Advantages

Extremely high resolution (both space and time)
Rapid

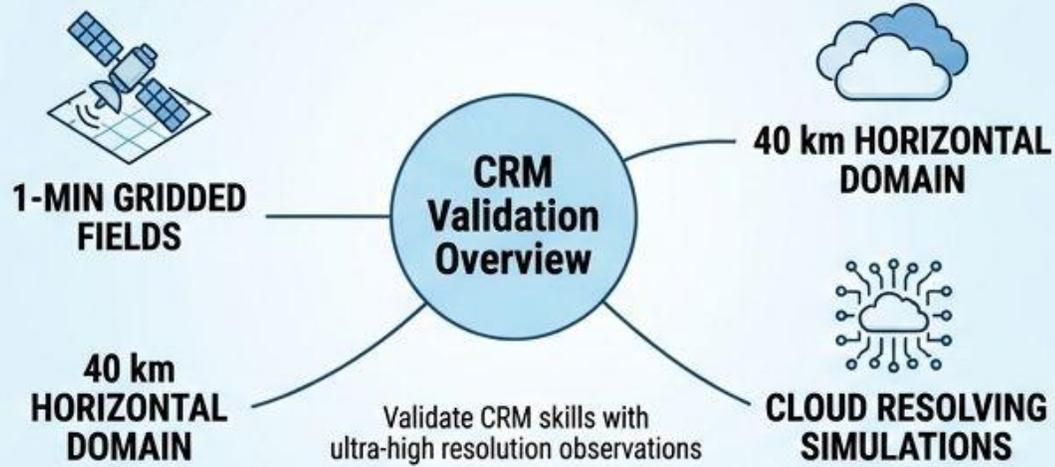

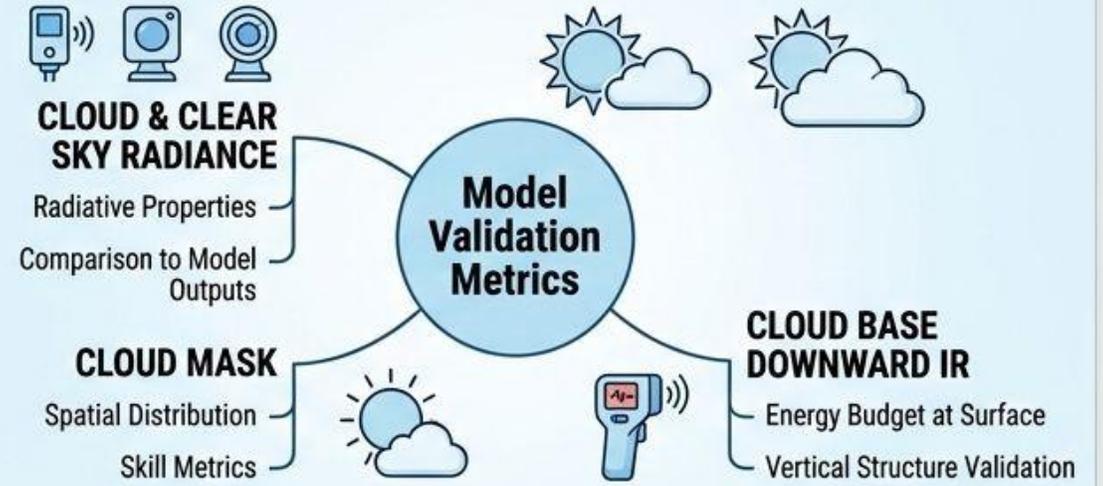

Spatial distribution (e.g., 40x40 grid cells)
